Subscriptions and back-issues
A year’s subscription to TCP/SNA Update, comprising four quarterly issues, costs $190.00 in the USA and Canada; £130.00 in the UK; £136.00 in Europe; £142.00 in Australasia and Japan; and £140.50 elsewhere. In all cases the price includes postage. Individual issues, starting with the March 2000 issue, are available separately to subscribers for $49.50 (£33.00) each including postage.

TCP/SNA Update on-line
Code from TCP/SNA Update, and complete issues in Acrobat PDF format, can be downloaded from http://www.xephon.com/tcpsna; you will need to supply a word from the printed issue.

Disclaimer
Readers are cautioned that, although the information in this journal is presented in good faith, neither Xephon nor the organizations or individuals that supplied information in this journal give any warranty or make any representations as to the accuracy of the material it contains. Printed in England.
Remote printing using JES/328X

Many installations using remote printers use the JES/328X print facility to satisfy their printing needs. The article is aimed at beginners who wish to implement a remote printer quickly. Implementation is discussed based on a simple example of an LPAR (LPARA) having a channel-attached 3174 establishment controller and remote printer connected to the 3174. It is assumed that JES/328X is already installed and is available for use. VTAM, JES2, and JES/328X are the major participants in remote printing. Remote printing takes places by LU–LU communications as shown in Figure 1, and the LU details are:

- PLU (Primary LU) – JESLU
- SLU (Secondary LU) – RMT10
- TLU (Tertiary) – PRTLUs.

To implement this arrangement, certain definitions are required

![Figure 1: Remote printing](image)
in JES2, JES/328X, and VTAM. The definitions may vary slightly from OS version to version. Here the version considered is OS/390 V2R10. The use of discretion is advised in applying the definitions given below to their installation.

**JES2 PARAMETERS (JES2PARM)**

The following definitions are required in the JES2 parameters for remote printing:

```
APPL(JESLU)  NODE=1

RMT1Ø  DEVTYPE=LUTYPE1,
       SETUP=PDIR

R1Ø.PR1  WS=(W,R,Q,PMD,LIM/F,P),
         PRWIDTH=132,
         CKPTLINE=72,
         NOFCBLOD,
         CLASS=Q,
         ROUTECDE=LOCAL,
         CKPTPAGE=1
```

**VTAM DEFINITIONS**

The following VTAM application definitions are required for remote printing.

**Primary LU (JES2 application definitions):**

```
APPLJES2  VBUILD TYPE=APPL
   *
JESLU  APPL  EAS=1Ø,
       ACBNAME=JESLU,
       AUTH=(ACQ),
       VPACING=1Ø
```

**Secondary LU definitions:**

```
RMT1Ø  APPL  EAS=1,AUTH=ACQ,MODETAB=MTJSX,DLOGMOD=JES4Ø96,VPACING=2
```

**Tertiary LU definitions:**

```
L31LØ32Ø  LBUILD
   PRTLU  LOCAL  CUADDR=328,ISTATUS=ACTIVE,DLOGMOD=DCS4KN,TERM=3286,
       X
       MODETAB=MTBAZ,FEATUR2=PRINTR
```
JES/328X PARAMETERS

The following definitions are required in the JES/328X parameters for remote printing:

A,SLU=RMT1Ø,PLU=JESLU,TLU=PRTLU,LUTYPE=Ø,DEVICE=FAM1
F,SLU=RMT1Ø,JES=JES2,CONSLOGP='SYS1.BAZ',CANCEL='$C PR1'
F,SLU=RMT1Ø,BUFSIZE=2Ø48,ERRMSG=ALL,CLSDELAY=Ø,LOGMODE=DSC4KN
F,SLU=RMT1Ø,INITFORM=IGNORE,RETRYDEL=3ØØ
F,SLU=RMT1Ø,XLATE=BASE,BASE=STD
*S,RMT1Ø

GETTING THE PRINTER WORKING

To get the remote printer working do the following:

1. Activate APPLJES2
2. Issue console command $S LOGON1
3. Activate APPLRMT
4. Activate Tertiary LU
5. Start the JSX started task.

After successfully issuing the above commands, datasets can be printed by using commands like PRINTDS with an appropriate output class.

A mainframe-centric comparison of KVMs

If you have ever connected to a mainframe from a workstation equipped with a Keyboard-Video-Mouse (KVM) switch, frustration is probably the best word to describe the experience. In my 2002 side-by-side hands-on comparison of 10 KVMs, it was clear to me that few, if any, had been tested with 3270 emulation software.
Since then, not much has changed in the KVM market. Newer models offer USB cabling instead of the separate PS/2 keyboard and mouse connections that are standard on the products reviewed here.

WHY KVM?

Whether you’re building a Network Control Centre (NCC) or just running a couple of workstations as a test network of your own, having a keyboard, mouse, and monitor for each machine just isn’t practical. Quite apart from the issue of desk space (footprint), there’s no ergonomic solution to frequently moving between two physical keyboards and mice.

Enter the Keyboard-Video-Mouse (KVM) switch, which allows one or more keyboards, mice, and monitors to control two or more computers. However, it’s often more practical to share only the keyboard and mouse, retaining a monitor per computer. As we’ll see, KVMs work even better in that environment.

THE EMPHASIS IN TESTING

KVMs were not built with mainframes in mind. At least, not the way I use workstations to access mainframes. I am still heavily committed to the use of the PC’s left and right Ctrl keys as 3270 Reset and Enter, respectively, based on the position of those keys on every 3270 terminal that was ever made by IBM.

And that creates a problem on many KVMs, because many use one or both of the Ctrl keys as part of a hot key sequence to perform special functions, such as switching between computers. Admittedly, you generally have to hit Ctrl twice before you run into trouble, but I find myself doing that a lot.

A related problem with some KVMs affects the use of Ctrl-click and Shift-click, where click refers to a left-button mouse click. These are both standard Windows actions to extend a current selection to include more items in a list.

Any, even subsecond, delay in the KVM’s transmitting the Ctrl or Shift to the computer often means it will arrive after the
mouse click. Accepted alone, the mouse click selects the current item and deselects any previous items – which can be very inconvenient.

WHAT WAS TESTED

The focus is on the low end: two- and four-port KVMs. At first glance, it may seem senseless to test two- and four-port models from the same manufacturer, especially the ones that look almost identical. But, as we’ll see, looks can be deceiving. Mainframe users may find a four-port model works quite well even when its two-port sibling is rather annoying.

When testing began in 2001, the emerging standard was PS/2 connections for both the mouse and keyboard. And that is what we tested. In 2002, USB KVMs began emerging, where the mouse and keyboard still plug into PS/2 ports on the KVM, but the connections from KVM to workstation ports are USB. After the formal tests, the Belkin was informally tested as a USB KVM.

BUYING ADVICE

Be sure to include the cables when preparing cost estimates for KVMs, especially USB KVMs. Here are a few things I learnt during testing:

• It is important to consider user ergonomics (easy reach) when placing a frequently-used KVM.

• The cables must be long enough!

• None of the USB KVMs I looked at required the more expensive USB 2.0 cables.

• All of the USB KVMs I looked at required a cable with a USB B plug on one end, rather than the more common USB A to USB A cable.

• Combined monitor/USB cables often cost little more than an equivalent monitor-only cable and are slightly cheaper than PS/2 KVM cables.
THE TESTS THEMSELVES

With the exception of the one AESP unit that requires power, all tests were performed without power, even when a power adapter was supplied with the KVM. There was never any indication that external power would have affected the test results.

One subtle difference between keystrokes:

- key-key means both keys are held down at the same time.
- key key means that each key is pressed in sequence.

The term ‘oriented’, referring to KVM cables, indicates that the round keyboard and mouse connectors are flat on one side to help line up the DIN connector with the plug. Once you get used to it, you can look at the position of the plastic key in the plug and automatically rotate the connector to the right place first time every time.

Figure 1 displays the observations and test results in table format.

KVM MANUFACTURERS

Because of the large number of products available in the marketplace, not all low-end KVMs were tested. But a fairly comprehensive list of KVM manufacturers was identified (see below). KVMs come in all sizes and shapes, and most of the companies listed specialize in certain segments of the market. KVM manufacturers we found were:

- AESP – http://www.signamax.com/signmax1_network/kvmswitch.htm
- Apex – now Avocent

CONCLUSIONS

During testing, it quickly became apparent that manufacturers had not tested their KVMs with 3270 emulators, at least not in the manner that many mainframe users use them. In fact, some product managers were quite interested in my test results, some going as far as planning changes for future models.

KVMs, at least the two- and four-port models examined here, have their limitations. If you look carefully at the test results, you’ll see that only one KVM correctly handled a power up/boot/start-up of a workstation when the monitor was in use for the entire period by another workstation. All the rest returned the maximum monitor resolution and screen refresh rate handled by the KVM, rather than the maximum handled by the monitor.

This makes it easy to inadvertently set the monitor resolution above what the monitor is capable of. But there’s another implication that had me scratching my head for a day or two. Like me, you have probably been unaware that increasing the monitor resolution to a point where your monitor can no longer handle the current screen refresh rate will result in Windows automatically decreasing the rate of screen refresh. But this happens only if Windows has the correct values for your monitor’s maximum screen refresh rate for each monitor resolution.

I have yet to find an affordable two-port KVM with the functionality I’ve been looking for. I want to view both workstations simultaneously, using two monitors and one keyboard and mouse, just as a technical writer would, viewing a mainframe screen while writing documentation with work processing on another workstation.

Ergonomically, I want the selected computer on the monitor
right in front of me and the ‘other’ computer on the monitor to the side. And I wanted to be able to switch with the touch of a single button. Recently, there were rumours of high-end KVMs with this capability, so maybe it will eventually filter down to the low-end.

IBM’s Communications Server for Linux Version 6.2

Communications Server for Linux, announced in May 2004 with general availability as of June 2004, is now the latest, and by far the most intriguing, member in IBM’s extremely ‘blue blooded’ Communications Server family, which has now been around for nearly 20 years – having started off as an OS/2 component. Ironically, one of the major roles envisaged for this new version is to provide, via an inspired Remote Client API capability, an attractive migration path for customers with OS/2-based SNA clients that now want to port these ‘legacy’ client applications, unchanged, to Windows or Linux.

Communications Server for Linux is currently available in two distinct versions – z/Linux and Linux for Intel. Thus the feature-packed Communications Server (CS) ‘gateway’ package, with its legendary tn2370(E) gateway, EE functionality, APPN support, and DLUR requestor, is now available on Windows (2000, 2003, and XP), AIX, z/OS (where it also includes the pivotal ACF/VTAM component), z/Linux, and Linux for Intel. Note, however, that Communications Server’s Linux support does not extend to IBM’s highly strategic (and mid-range converging) POWER-based servers, which now include the new i5s (within the iSeries), the p5s (within the pSeries), as well as the recently-announced, natively Linux, IBM OpenPower 720.

When it comes to CS on POWER, one has to remember that
Communications Server, despite its complexity, in the end is still just a Linux application. While one obviously has to port Linux to a specific platform, in this instance POWER, once Linux is available on a platform, supporting an application on top of Linux is just a case of testing and certification. And this is where with Linux, as illustrated here, we are once again running into the frustrating conundrum encountered with Java Web-to-host offerings, ie write once but needing to be diligently tested on every platform. The good news, however, is that IBM is acutely aware of this omission and intends to rectify it. The other good news is that IBM has added the z/Linux version, at no additional cost, to the WebSphere Host Integration Solution (HIS) bundle – this is, therefore, the first time a mainframe gateway has been available with HIS. Current HIS customers have the option of obtaining it, again at no charge, from IBM, though you may want to read the rest of this article before jumping at this offer.

IT IS NOT QUITE AS WONDERFUL AS YOU MIGHT EXPECT

Deciding how one can gainfully use CS/Linux, which at first blush looks highly compelling, may, however, not be as clear cut and obvious as one might initially think. For a start, the z/Linux offering might end up being considerably more germane to VSE/ESA and z/VM customers than to those running z/OS. The crux of the issue here, as this readership will immediately appreciate, has to do with cross-LPAR networking. As we know, mainframe networking is now optimized for IP-based networking; with HiperSockets, the fastest means of realizing inter-LPAR communications, being totally IP-centric. It is this bias towards IP-based communications that makes it difficult to justify where and how to use these Linux offerings.

In the end, as has always been the case when it comes to mainframe SNA, everything revolves around ACF/VTAM. CS for z/Linux, though including a plethora of APIs, among which are CPI-C, HACL for Java (à la Host On-Demand), LU-level session APIs, and many APPC interfaces, does not include ACF/VTAM functionality. VTAM functionality is available only
on z/OS (via CS), VSE, and VM. Thus, as with other versions of CS since around 1997 including CS for z/OS, one of the key attractions of CS/Linux, whether on the mainframe or an Intel server, is going to be the powerful tn3270(E) server with its integrated support for SSL security – critical for nearly all contemporary Web-to-host solutions whether it be applet-based emulation (eg IBM’s HoD), host publishing (eg IBM’s HATS V5) or host integration (eg NetManage’s OnWeb 7.1). And that is where the dilemma begins.

The I/O configuration of a ‘tn’ server is very straightforward and immutable. It ‘speaks’ TCP/IP on the network side (ie downstream) and has to speak SNA(/APPN) on the mainframe side. Thus if you want to use CS for z/Linux as a scalable, cost-effective ‘tn’ server you have to have a way to ‘bridge’ the SNA/APPN (on the upstream side) with the LPAR running ACF/VTAM (and with it, all the major mission-critical applications of the CICS, IMS, DB2 ilk). Technically this is not a problem, given that there are multiple proven means for cross-LPAR communications including real or virtual Channel-to-Channel (CTC) connections, as well as shared LANs using OSA(-Express). Note that HiperSockets, however, is not a direct option – unless, of course, you want to add the extra step (and overhead) of using EE between the LPARs. The issue thus boils down to performance and efficiency, particularly when it comes to z/OS – given that it is possible to have the ‘tn’ server implemented within the z/OS LAPR, which eliminates the need for a cross-LPAR ‘hop’.

DEFINITE RECOMMENDATIONS FOR VSE AND VM CUSTOMERS

Since there is no native CS offering for VSE and VM (and hence no IBM-provided ‘tn’ server or EE), the dynamics and decisions are very different from those faced by z/OS customers. CS for z/Linux provides VSE and VM customers with all the advantages (eg scalability and resilience) of a mainframe resident ‘tn’ server, EE, and APPN node capability – albeit on a ‘surrogate’ LPAR. VM and VSE customers that need a high-capacity, high-performance tn3270(E) server (ie
250 or more concurrent sessions with sub-5-second performance) should seriously consider the z/Linux option. With this option they can gainfully consolidate multiple networking essentials, including their Web server, tn3270(E) server, host publishing/host integration server, on a single mainframe LPAR, and most likely use virtual CTC for their inter-LPAR networking.

The issues are more convoluted when it comes to z/OS. Consolidating various networking components (eg Web servers, application servers, Web-to-host schemes) hitherto running on external servers on a single mainframe LPAR is a very strategic move given that it simplifies complexity and ensures painless scalability. In this context it is also fair to say that having a ‘tn’ server on z/Linux is likely to be a better option for most medium to large z/OS shops than having it on an external server – particularly a Windows server. But then the question becomes, why implement it on a z/Linux LPAR when it could be installed, co-located with VTAM (given that CS is already installed on the z/OS LPAR in order to obtain the VTAM functionality)?

To this end it is also important to factor in that IBM does not recommend that customers who already have a z/OS tn3270(E) server think about migrating that server to z/Linux. IBM cites performance, robustness, and the exploitation of z/OS features such as Sysplex and VIPA as reasons why they recommend sticking with z/OS rather than moving to z/Linux. That in itself should give you some valuable guidance as to what you should be thinking about when weighting ‘tn’ on z/OS versus z/Linux.

**BOTTOM LINE**

CS for Linux is certainly a welcome addition to the strategic CS family – though the lack of support, at least at present, for Linux on POWER is frustrating. CS for Linux is a compelling migration option for customers with OS/2 SNA applications as well as those that are using Windows-based SNA Gateways.
(eg Microsoft’s Host Integration Server). It is also an extremely attractive proposition for VSE and VM customers. z/OS customers, however, may not find it that appealing. But, again, they should evaluate it carefully to see whether there are any cost savings they might be able to realize – albeit by sacrificing some performance and efficiency.

@FTPPUT edit macro

Moving source back and forth between ISPF and distributed platforms can be a time-consuming activity. So I wrote a pair of edit macros to make my life a little easier. In the September issue of TCP/SNA Update we looked @FTPGET (see Issue 55); this issue we look at @FTPPUT.

@FTPPUT will take the current contents of an edit session and PUT it to any FTP server. Like @FTPGET, it presents a small pop-up to get the destination information and sends the data.

@FTPPUT will capture the FTP output and present it in browse, only if the FTP session has a problem. The macro is fully self-contained and needs to be placed in a PDS in the TSO SYSEXEC concatenation. It could also be placed in SYSPROC, but you will have to delete the first line so you have the required REXX comment on the first line.

FTPPUT

Enhancing mainframe-to-mainframe Enterprise Extender (EE)

Enterprise Extender (EE), an integral component within all of IBM’s Communication Server ‘gateway’ and PComm emulation offerings, has, since 1996, always been (without exception) IBM’s recommendation for routing SNA/APPN traffic across IP networks – whether they be intranets, VPNs, extranets, or even the Internet. Rather than in anyway being a partisan marketing-oriented posture, this unwavering endorsement of EE by IBM is based on multiple, extremely germane, SNA-centric, technical factors.

For a start, EE is the only SNA-over-IP transport scheme that supports \textit{bona fide} SNA LU name-based, end-to-end routing (i.e. the so-called ‘SNA routing’ performed by SNA subarea
nodes, in particular ACF/NCP Type 4 nodes). Hence IBM’s partiality for EE over DLSw and AnyNet, neither of which supports SNA routing. Furthermore, DLSw, the router-oriented mechanism for transporting SNA/APPN across IP backbones, is not available on mainframes. Thus, DLSw-based SNA-over-IP transport can, at best, only start at a channel-attached router. This precludes QDIO mode operation with Gigabit Ethernet OSA-Express ports, the fastest and most efficient of modern mainframe I/O mechanisms, given that QDIO supports only IP-based traffic. To get around this limitation, DLSw fans, ironically, recommend using EE between the channel-attached router and the mainframe – given that Cisco routers also support EE, which is now an Internet standard in the form of RFC 2353, though they call it SNASw. EE, in contrast to DLSw and AnyNet, also supports SNA CoS traffic prioritization.

When combined with the Extended Border Node functionality (another standard feature of Communications Server for z/OS), EE is also the only IBM-mandated solution, at present, for replacing some 3745/3746-centric SNI configurations with IP-based networking across OSA-Express adapters. This is clearly reiterated in IBM’s June 2004 Statement of Direction Update on SNA Support. The bottom line here is that given all these EE-only capabilities when it comes to SNA-over-IP, it is not surprising that IBM consistently refers to EE as offering the best of both worlds when it comes to SNA/APPN and IP.

**SO SHOULDN'T EE BE MORE POPULAR?**

Despite its many incontrovertible strengths, and IBM’s relentless backing of it, EE is not nearly as prevalent in the TCP/SNA world as one would expect. Given that TCP/SNA professionals are invariably pragmatic and pedantic (to a fault) when it comes to networking technology, there have to be some very valid reasons why they continue to drag their heels when it comes to embracing EE – regardless of IBM’s efforts to encourage more widespread usage. In the case of enterprises migrating to SNA-over-IP, there are four key
reasons why TCP/SNA professionals have shied away from EE to date. These are:

1. Since EE is HPR-based, using EE to route SNA-over-IP requires the definition and activation of appropriate APPN nodes as well as DLUS/DLUR functionality.

2. DLSw, despite its limitations vis-à-vis SNA routing, SNA CoS, and QDIO, is a well understood, highly proven, and relatively easily implemented mechanism that does not require any changes to the existing SNA-related definitions – and certainly does not require the implementation of APPN nodes.

3. EE does not use TCP – thus making firewall traversal, network management, and SSL-based security both bifurcated and difficult.

4. EE does not support multiple IP stacks within the same LPAR, thus foiling large customers who now prefer to segment their IP-centric network into multiple operational sub-nets (eg each serving a particular corporate division or extranet population) using separate IP stacks for each sub-net.

While the first two objections above will continue to hold sway when it comes to ‘branch office’ networks, EE, despite its APPN requirements, is still the only real option for optimal mainframe-to-mainframe networking – whether it be cross-domain or SNI. The primary reason for this is the lack of DLSw functionality on mainframes. The second reason is that throughput is invariably a requirement when it comes to inter-mainframe networking and QDIO mode is the best way to realize such performance. So one way or another, with 37xxs now officially discontinued and 37xx spares getting scarce, TCP/SNA professionals looking at mainframe-to-mainframe connections are being forced to consider EE – particularly as an SNI replacement scheme.

It is at this juncture that the last two EE-related objections raise their head. Fortunately there is, at last, an attractive
solution for both of these problems when it comes to mainframe-to-mainframe EE: the recently-announced (August 2004) Apias 3.1 offering from William Data Systems (www.willdata.com). Many of you are no doubt already familiar with William Data Systems thanks to the popularity of their mainframe-based EXIGENCE and IMPLEX network management offerings and the innovative RouteView tool for graphically managing ACF/VTAM and ACF/NCP Path Tables.

APIAS 3.1 ADDS MUCH-NEEDED FEATURES

Apias 3.1, which works alongside EE (as peer EE node), in essence imbues IBM’s standard Communications Server for z/OS-based EE with three additional features:

1. Transportation of EE traffic, mainframe-to-mainframe, using TCP/IP – rather than the User Datagram Protocol (UDP) normally used by EE.
2. End-to-end authentication and data encryption using SSL with digital certificates.
3. Ability to use multiple IP stacks with EE, thus enabling customers to securely partition their IP networks into sub-nets.

Of these features, the pivotal one is that of TCP/IP enabling EE. There are four key reasons why it is often best to use EE with TCP/IP, instead of EE’s native UDP. These are:

1. Controlled firewall traversal through already open and closely monitored TCP ports.
2. Ensuring that EE connections and traffic can be continually monitored and managed alongside other TCP/IP traffic, in particular tn3270(E), HTTP, and FTP, rather than as a separate EE-specific protocol.
3. The ability to use SSL’s end-to-end security.
4. Reliance on a connection-oriented, guaranteed delivery mechanism in line with the traditional data link schemes hitherto used for SNA connections.
USING TCP RATHER THAN UDP IS PIVOTAL

EE opting to use UDP rather than TCP can be attributed to a fit of ‘irrational exuberance’ on the part of some well-intentioned technocrats in what were the early and heady days of SNA/IP integration – when all today’s headaches relating to security and management were still way out on the horizon. The preference for UDP stems from the fact that HPR, in marked contrast to SNA and APPN, has a powerful, connectionless, Layer 2 routing mechanism known as Automatic Network Routing (ANR). The architects of EE wanted to highlight and preserve this connectionless routing theme of HPR – given that EE is meant to be HPR-over-IP.

UDP is IP’s connectionless datagram mechanism. TCP, on the other hand is IP’s connection-oriented (ie session-based), guaranteed-delivery transport mechanism. UDP works and works well. But it is not TCP/IP and that is the rub.

Many corporations, quite rightly, are hesitant to open the UDP-related ports (ie ports 12000 to 12004) on their firewalls. UDP, as a connectionless protocol, is an ideal means for delivering malicious payloads and mounting denial-of-service attacks. EE’s reliance on UDP was thus a major impediment when it came to controlled firewall traversal. This is now no longer an issue with Apias 3.1.

TCP/IP is also, indubitably, the most widely used of the Internet protocols given that it is the basis for HTTP(S), FTP, SMTP/POP (ie e-mail), telnet, and tn3270(E)/tn5250. TCP/IP is the protocol that network professionals know best. It is the protocol that they continually monitor and manage using the IP monitors. It is the TCP/IP activity window that invariably has pride of place within most IP monitoring stations.

While high-end IP monitors do indeed provide unstinted support for UDP, it is still the case that UDP is a marginal minority protocol compared with TCP. With Apias 3.1, EE no longer has to be dependent on UDP. Instead EE can join the mainstream by using TCP (and SSL) like all the other major corporate applications.
BOTTOM LINE

While DLSw is likely to prevail when it comes to branch networks, EE indubitably is the optimum solution for mainframe-to-mainframe SNA-over-IP connections, whether it be SNI or just straightforward cross-domain. EE’s use of UDP was a problem particularly when it came to security and network management. Apias 3.1 is a way to easily overcome these hitherto frustrating limitations of EE. Apias 3.1 is an ACF authorized z/OS task that runs in its own address space. All of its networking functions are realized using a standard IBM IP stack. Apias 3.1 is a well-behaved ‘sockets’ application that, moreover, relies exclusively on documented and open IBM APIs. Thus, Apias 3.1 in no way compromises the integrity, reliability, or stability of EE, IBM’s Communications Server, or IBM IP stacks. Therefore, if you are planning to use EE for mainframe-to-mainframe communications, you should definitely evaluate Apias 3.1 as a must-have adjunct to EE.

FTP tool for mass data transfer

Data transfer from mainframe to PC or any server location is a time-consuming process. If the volume of data is huge, it may take as much as several hours to transfer. In this article I have outlined the difficulties associated with the conventional data transfer facility and an approach through which one can cut the data transfer time substantially.

In on-line mode, file transfer from a mainframe is accomplished using the IND$FILE transfer facility provided by the ISPF command shell. Typically, all mainframe emulators provide an interface to transfer files between the host (mainframe) and PC. This facility is good when the amount of data to transfer
is small. With large amounts of data to transfer it poses two major issues:

1. The time taken to transfer the data is enormously large because the rate of data transfer through IND$FILE is very low.

2. The TSO terminal/emulator remains locked as long as the transfer is in progress.

Both the above issues could be resolved using customized FTP jobs in online or batch mode. The customized FTP job does not require the use of a mainframe emulator. Consequently, the issue of a locked emulator session never happens. It connects to the mainframe by establishing a normal FTP session from a DOS command prompt. One can write a customized FTP tool in any text-processing editor available on one’s PC. It could then be executed on any other PC provided the PC is connected to the LAN. The whole idea is that the mainframe connection must be available on the LAN for FTP to work properly.

Writing customized FTP jobs is a simple task. The first step is to write an actual FTP download or upload job. The steps below describe how to write the FTP download/upload job:

1. Open a fresh file in Notepad or any other text-processing editor.

2. Put the following lines into it:

   OPEN <IP address of the mainframe OR its alias>
   <USERID>
   <Password>

---

Please note that the correct contact address for Xephon Inc is PO Box 550547, Dallas, TX 75355, USA. The phone number is (214) 340 5690, the fax number is (214) 341 7081, and the e-mail address to use is info@xephon.com.
GET <Mainframe file name to be transferred to PC> C:\FILE1.TXT
PUT <Mainframe file name to be received from PC> C:\FILE2.TXT
BYE

Here, replace <IP address of the mainframe OR its alias> with the actual IP address of the mainframe. Similarly, replace <USERID> and <Password> with the USERID and password that you use to log-on to a mainframe session.

GET is an FTP command to transfer the data from the host to a PC. Replace <Mainframe file name to be transferred to PC> with an actual file name, within quotes. PUT is just the opposite of GET. You can use multiple GET and PUT statements in the same FTP job to transfer multiple files.

The BYE command terminates the session at the end of data transfer. If you do not want to terminate the session automatically, do not write the BYE command.

The job will download the files to the C: drive of your PC. If required, change the destination appropriately.

3 Save the file with a .TXT extension. You can give this file any name you wish. Let’s assume it is called loginftp.txt.

The second step is to write the driver batch program that would trigger the actual FTP job. The steps below describe how to write a driver program:

1 Open a fresh file in Notepad or any other text-processing editor.

2 Put the following line into it:

    ftp -s:loginftp.txt

    Note that loginftp.txt is the same file that we just created.

3 Save the file with a .BAT extension. You can give this file any name you wish. Let’s assume it is called DataTransfer.BAT.

Now the customized FTP job is ready. Simply double-click the DataTransfer.BAT file. It will establish the FTP session with
the mainframe and start uploading or downloading the data until the data transfer completes.

In an experiment that involved the transfer of files from a mainframe to a PC using the conventional method and the FTP job, we found that the latter to be 800 times faster than the former.

Using FTP trace for diagnostics

The FTP trace can let you, at a diagnostic location at the central site, view FTP commands entered from a remote location. This can be quite useful when helping users in diagnosing problems. They may have received error codes or entered commands improperly. You just have to tell them to re-create the problem scenario, and this time you can watch what they are doing as they do it.

The way you do this is by using the FTP trace facility. The first thing that has to be done is to set up SYSLOGD.

USING SYSLOGD

The syslog daemon (SYSLOGD) can capture informational or debugging messages about the operation of system functions or socket applications. You can run the syslog daemon as a started task, bring it up under Unix System Services or even as a job. You must configure SYSLOGD using a configuration file such as the one shown below:

(C) COPYRIGHT International Business Machines Corp. 1995,1999  
# All Rights Reserved  
# Licensed Materials - Property of IBM

# /etc/syslog.conf - control output of syslogd
#
# A # sign denotes a comment.
# Each line of this file must contain at least two parts:
# A message source list and a destination
#
# (Several comment lines have been deleted here)

# The following has been uncommented and can be used in an
# actual installation. The target output file MUST EXIST before
# the syslog daemon is started.
#
# Log all entries to /tmp/syslog.log
    *.*       /tmp/syslog.log
    *.info    /dev/console
#

Notice the statements:

    *.*       /tmp/syslog.log
    *.info    /dev/console

The statement ‘*.* /tmp/syslog.log’ will route all messages to
the file /tmp/syslog.log. This file must exist before starting
SYSLOGD. The statement ‘*.info /dev/console’ will route all
messages with a priority of information or above. Syslog
messages can vary from a priority of critical to debug. These
priorities are defined in RFC3164.

**CAUTION!**

Make sure that you do not have debug messages going to the
console from syslog! The routing should be priority information
or higher. If you turn on FTP tracing and you are routing all
messages to the console, you will have a very high risk of
flooding the console and causing serious system problems.

The configuration parameter shown below in the syslog
configuration file controls the types of message that will go to
the console:

    *.info    /dev/console
OPERATIONAL CONSIDERATIONS

Starting an FTP trace varies from z/OS to OS/390. For z/OS, to start tracing the FTP task on the mainframe, enter from the system console:

```
MODIFY ftptaskname,DEBUG=(CMD,USERID(user id*))
```

for the FTP server and user id you wish to trace. For example:

```
MODIFY FTPD1,DEBUG=(CMD,USERID(WLJ*))
```

For OS/390, use the command:

```
MODIFY ftptaskname,UTRACE=user id
```

After the trace has been successfully started, you may ask the user to use FTP so you can watch it for any problems.

Finally, stop the FTP trace. For z/OS, enter from the system console:

```
MODIFY ftptaskname,NOTRACE
```

For OS/390, the command is:

```
MODIFY ftptaskname,NOUTRACE
```

FTP LOGGING WITH Z/OS 1.4

With z/OS 1.4, the FTPLOGGING statement in FTP.DATA for the FTP server can be used to indicate whether the FTP server should log FTP server activity. The following types of activity are logged:

- Connectivity
- Authentication
- Access
- Allocation.

These messages are similar to the FTP trace statements. The drawback to this method is that you must be on at least z/OS 1.4. Many installations are not yet at this release level.
You must also create logs for all users – this could create a great deal of data. Lastly, this feature cannot be turned on and off dynamically. One could modify the FTP.DATA and then restart the FTP server to achieve dynamic logging – but this seems a little brutal.

**FTP SERVER TRACE**

Now, how can you actually use the FTP trace? Figure 1 shows a sample FTP server trace with two attempts at file

Figure 1: Sample FTP server trace
transmission. An FTP server trace allows you to view any commands the user enters at their remote PC as they enter them. This will allow you to diagnose the problems the user is experiencing when submitting FTPs. You will be able to see exactly what files they are trying to send or receive. You can also view any error messages they receive.

Then we created the output shown in Figure 1 with some technology that we use. You can also browse the syslog output for these messages.

The log is presented in reverse chronological order. Some interesting events in the log are as follows:

- Entry # 22 – user NALI starts a new FTP session.
- Entry # 20 – the password is successfully entered.
- Entries # 19–10 – the user gets to the desired file to transmit.
- Entry #9 – the user asks for file SPFLOG1.LIST.
- Entry #8 – the file is being used by another program. The return code 450 is returned.
- Entry #5 – the user asks for file SRCHFOR.LIST.
- Entry #3– the file SPFLOG1.LIST is transmitted successfully.
- Entry #1 – the FTP session is terminated.

**SUMMARY**

The FTP trace can be quite useful in assisting remote users from the central site. Simply remember a few commands and then browse the syslog output!

Computer Associates has announced the availability of new Measured Workload Pricing for the company’s mainframe management software products. This combination of usage-based pricing and best practices management capabilities enables CA customers to maximize the performance of their data centre investments.

Measured Workload Pricing bases licensing costs on measured system usage (rather than total potential hardware capacity) enabling customers to align IT spending with changing business requirements. Customers can establish licence costs based on measured levels of usage, while reserving the ability to increase usage as needed to support growing demand.

Measured Workload Pricing is based on quarterly reports generated by IBM’s native Sub-Capacity Reporting Tool (SCRT).

The solution sets include network management, which is said to maximize operational performance through the integrated management of SNA and TCP/IP networks, overcoming fragmented management processes that diminish effectiveness and drive up the cost of network ownership.

For further information contact:
Computer Associates One Computer Associates Plaza, Islandia, NY 11749, USA.
Tel: (631) 342 6000.

Aton International has updated its TN3270 terminal emulation package for Pocket PCs running Windows Mobile and Pocket PC Phone Edition. The product uses the TN3270 terminal protocol to connect to CICS, VM/ CMS, or MVS. The new version adds full-screen landscape mode, soft keyboard, and session switching, allowing access to mainframe and Web services data.

For further information contact:
Aton International, 731 Morgan Place, Los Altos, CA 94024-4901, USA.
Tel: (650) 938 9328.

Attachmate has announced ‘next generation’ emulation with EXTRA! Mainframe Server Edition Version 8.0 for Windows XP.

The product offers a security framework to safeguard mainframes, centralized management from anywhere on the network (including the mainframe), portal integration of host access clients, and integration with Microsoft Office applications to boost user productivity.

Because mainframes participate in services-oriented initiatives that expose them to new threats, the product adds enterprise security.

For further information contact:
Attachmate, 3617 131st Avenue SE, Bellevue, WA 98006, USA.
Tel: (425) 644 4010.
