Editorial panel

Articles published in *VM Update* are reviewed by our panel of experts. Members of the panel include John Illingworth (UK), Reinhard Meyer (Germany), Philippe Taymans (Belgium), Romney White (USA), Martin Wicks (UK), and Jim Vincent (USA).

Subscriptions and back-issues

A year's subscription to VM Update, comprising twelve monthly issues, costs £175.00 in the UK; \$265.00 in the USA and Canada; £181.00 in Europe; £187.00 in Australasia and Japan; and £185.50 elsewhere. In all cases the price includes postage. Individual issues, starting with the January 1990 issue, are available separately to subscribers for £14.50 (\$22.50) each including postage.

Copying permits are available from Xephon in the form of pressure-sensitive labels, for application to individual copies. A pack of 240 labels costs $\$36 (\pounds24)$, giving a cost per copy of 15 cents (10 pence). To order, contact Xephon at any of the addresses above. *Printed in England*.

VM/ESA Version 2 Release 3.0

OVERVIEW

VM/ESA Version 2 Release 3.0 became available at the end of March 1998. With an integrated TCP/IP communications suite, Network File System (NFS) access to VM files, Java Virtual Machine capability, and Message Queuing Interface (MQI), VM/ESA's role as a platform for business solution deployment in networked environments is strengthened further. This article is my personal view of the most interesting highlights from a technical standpoint. Formal details are contained in the IBM European Announcement Letter, ZP98-0203. Other useful information about the announcement can be found by visiting the VM home page on the World Wide Web at http://www.vm.ibm.com.

Building on the previous release, VM/ESA Version 2 Release 3.0 provides a Year 2000-ready base for applications. In addition to expanded network computing support, the new release also provides:

- Enhanced TCP/IP for VM/ESA FL310, including NFS server support for CMS mini-disk, Shared File System, and Byte File System files.
- Additional OpenEdition Unix programming interfaces.
- Java Virtual Machine, JDK 1.1.1, and NetREXX.
- Message Queuing client interface.
- Integration of CMS Pipelines PRPQ.
- Extensions to support for Year 2000.
- Full integrated IBM Language Environment (LE).
- OS/390 guest Parallel Sysplex Testing support.

The basic procedures for installing and servicing VM/ESA Version 2 Release 3.0 have not changed. However, the contents of the system DDR images have altered as follows:

- The VM/ESA GUI feature is now part of the CMS component of VM/ESA.
- The Language Environment (LE) product is pre-installed on the system DDR.
- The 3800 Printer Image Library Source is pre-installed on the System DDR.
- The NLS features, OSA/SF, and VM Online Library are installed on the System DDR and can be optionally loaded during installation.
- TCP/IP, the TCP/IP NFS feature, and RSCS are pre-installed in a disabled state as part of the base VM/ESA.
- Two new EXECs have been added to automate several manual steps required during installation.

The sections that follow expand on the major functional enhancement areas in this new release of VM/ESA. Much of this information comes from the VM/ESA Version 2 Release 3.0 Announcement Questions and Answers at http://www.vm.ibm.com/vm230/vmv23qas.html.

TCP/IP FOR VM/ESA FL310

TCP/IP has undergone major enhancements and repackaging in VM/ESA Version 2 Release 3.0. Prior to this new release, TCP/IP and the TCP/IP Network File System (NFS) feature were separately orderable through IBM program product number 5735-FAL. Now the TCP/IP base product and the TCP/IP NFS feature are automatically shipped and pre-installed in a disabled state, as optional priced features in the base product DDR. Before enabling the code, the customer must ensure that required feature licences are in place. Other optional features of TCP/IP (for example TCP/IP source code) provided with previous levels of TCP/IP for VM are still available as separately orderable priced features of VM/ESA.

The following section details some of the key enhancements in TCP/IP FL310.

SMTP

Performance of the Simple Mail Transfer Protocol (SMTP) server is greatly improved. Laboratory tests have shown an increase in throughput of up to 3.4-fold for sample configurations. Further TCP/IP performance improvements are described in the VM/ESA Version 2 Release 3.0 Performance Report which can be downloaded from the VM home page on the World Wide Web at http://www.vm.ibm.com/perf/docs/vm230prf.html.

Network File System

In TCP/IP FL310 the NFS server supports the Byte File System and the Shared File System, as well as CMS mini-disks. There are several ways to obtain immediate benefit from this capability – for example, by NFS mounting an SFS directory from a workstation client, one could use PC-based Web publishing tools to place HTML and other Web content into production for immediate delivery by a VM Web server. NFS access to VM data is controlled through a VM user-id and password supplied on the NFS MOUNT command. The user-id is used by the NFS server to determine authorization for SFS files and directories. The corresponding UID and GID are used to determine access permission for BFS files and directories. Depending on a supplied start-up parameter, the NFS server can also allow or deny anonymous access. If anonymous access is allowed, an NFS mount to an SFS directory does not require a user-id if PUBLIC has been granted authority to that directory. Similarly, an NFS mount to a BFS directory does not require a user-id, if the default UID (-1) has permission to access it.

Since all authorization and permission checking is done by the file pool server, the protection is the same as when the files are being accessed from CMS.

Options exist on the MOUNT command to enable an NFS client to request data in the format it needs. The LINES option governs the translation of files between CMS record formats and the byte stream format used by NFS, and can be automated conditionally – based on the file name. Thus, with a single mount, a workstation user can view PROGRAM.EXE without the insertion of line-end characters by the

NFS server, while the file README.TXT can be read with line-end characters inserted so that it displays correctly.

The TRANS option allows the client to control whether EBCDIC/ ASCII translation should take place. This too can be made conditional based on the file name. The NLVALUE option allows the client to specify which character(s) should be used to represent line-end.

TN3270E

The TN3270E protocol (RFC 1647) support in TCP/IPFL310 provides for the creation of 3270 printer sessions as well as traditional display sessions. This allows workstation-attached printers to be accessed from VM over a Telnet connection. To the host application, the printer looks like a 3287 printer accepting 3270 data streams. TCP/IP defines a logical 3287 device to represent the printer, invokes an exit to attach the device to the appropriate service machine (normally RSCS), and then handles the data streams that flow between the server and the printer.

Long Fat Networks

TCP/IP extensions for high performance (RFC 1323) have been implemented to improve throughput over networks that have large bandwidth x delay values. A new DATABUFFERLIMITS statement in the TCP/IP configuration file specifies maximum send and receive window sizes that may be allocated for a TCP connection that is using window scaling. The statement has an effect only in networks containing other TCP/IP hosts with support for RFC 1323. Initiation of window scaling can be suppressed by inclusion of the NORFC1323 parameter on the ASSORTEDPARMS statement.

Multiple home addresses

TCP/IPFL310 supports RFC 1122, which allows multiple IP addresses to be associated with a single network link, as well as extensions for virtual hosting. The first home address specified for a link is its primary one.

Here is an example that shows how to code multiple home addresses

and how servers can handle a port on one virtual host or a port on all virtual hosts:

```
HOME
10.0.0.1 SomeLink ; Primary home address
10.0.0.2 SomeLink
10.0.0.3 SomeLink
...
PORT 80 TCP HTTPD ; All virtual hosts
PORT 10.0.0.2 80 TCP HTTPD ; One virtual host
```

CHECKSUM Assist

The System/390 hardware CHECKSUM feature is used (where available on the processor) to compute packet checksums.

Performance, diagnostic, and tracing facilities

Extensive performance instrumentation has been added to allow the performance of TCP/IP applications to be measured (APPLMON CP monitor records).

The VM Control Program is now aware when a logical device is associated with TCP/IP (ie is being used to access the system via Telnet) and provides the Telnet server name and client IP address in appropriate operator messages, command responses, accounting records, and ACI parameter lists.

Trace facilities have been enhanced to allow just selected devices, users, or IP addresses to be traced.

NETSTAT command

The NETSTAT command has been enhanced to display more information and provide greater selectivity. Command operands concerned are:

- ARP displays ARP cache entries.
- DELARP deletes ARP cache entries (restricted use).
- LEVEL displays processor type, VM/ESA, and TCP/IP levels.
- SELECT limits response output based on specific values, such

as a user-id or client name.

- POOL includes Xlate and IPRoute information.
- INTERVAL-enhanced to remove single panel display limitation.

New server virtual machines

The following new servers have been included:

- TFTP Trivial File Transfer Protocol (BFS only)
- BOOTP Boot Protocol
- DHCP Dynamic Host Configuration Protocol
- UFT Unsolicited File Transfer Protocol (RFC 1440).

The first three are intended primarily for use with the IBM Network Station. The latter supports receipt of files sent using the UFT protocol.

With the UFT or Sender-Initiated File Transfer (SIFT) protocol the receiver does not initiate the file transfer. UFT contrasts with other file transfer methods in that the sender of a file does not need an account or other form of registration on the target host system, and the receiving user may require fewer steps to retrieve the file(s) sent. Unlike traditional file transfer, UFT lends itself naturally to background or deferred operation, although it may be carried out immediately, or even interactively. This brings to IP-based networks the ability to send a file that is not a mail attachment to another user, thereby eliminating the need for the file to be processed by a mail user agent. In an NJE network, VM users have historically used SENDFILE as a simple, convenient way to transmit files to other users.

CMS NOTE and SENDFILE

The TCP/IP versions of the CMS NOTE and SENDFILE commands have been integrated into CMS to provide automatic support for TCP/IP electronic mail and file transfer.

Apart from minor additions to the syntax of the CMS NOTE command, several new options appear in the syntax of the CMS SENDFILE

command. Some that apply when the target node is an IP address are:

- SMTP the file is sent using SMTP without any encoding or MIME headers.
- MIME the file is sent using SMTP. The file is encoded in Base64 and sent as a single-part MIME data stream.
- UFTSYNC the file is sent to the remote host's UFT server directly from the user's virtual machine. If no UFT server is available on the remote host, the file will be sent using SMTP instead. The file is sent as a two-part MIME data stream. The first MIME part is a meta-file containing all the UFT information associated with the file (file-id, format, record length, etc). The second MIME part is the file data encoded in Base64 (a MIME-defined encoding format).
- UFTASYNC SENDFILE will send the file to another virtual machine identified in TCPIPDATA, from where it will be sent to the remote host's UFT server. This virtual machine acts like an agent and becomes the UFT client that connects to the remote UFT server.

Server configuration

Adding and replicating TCP/IP service machines has been simplified considerably through the use of a DTCPARMS file that contains tags (as in a CMS NAMES file) describing each of the TCP/IP servers. Here is a sample entry for an FTP server:

:nick.ftp :type.class :name.FTP Daemon :command.SRVRFTP :runtime.PASCAL :diskwarn.YES :anonymous.NO :ESM_Enable.NO :ESM_Validate.RPIVAL :ESM_Racroute.RPIUCMS

ADDITIONAL UNIX INTERFACES

165 additional APIs help simplify the porting of Unix applications to VM. The APIs added in this release, a subset of the XPG4.2

(X/Open Portability Guide) specification, were chosen because of requirements submitted by customers who are porting Unix applications and tools to VM and through analysis of the functions most often needed by applications ported to other IBM platforms. The new APIs include interfaces for inter-process communications, mathematical functions, and extra signal support.

Many older Unix programs use the FORK() function, which has not been available in VM/ESA. VM/ESA Version 2 Release 1 provided the SPAWN() function as a replacement for the combined use of the FORK() and EXEC() functions to create a new process for running a new program. Programmers porting Unix applications to VM have found that replacing FORK() calls with the appropriate supported functions is mostly trivial. Nevertheless, they would also find it helpful to be able to try the application on VM unchanged before undertaking a conversion. The FORK() function in VM/ESA Version 2 Release 3.0 will allow most applications that use FORK() to run on VM while they are being ported. Applications can use the FORK() function on VM/ESA in cases where an EXEC() function invocation follows the FORK(). This accommodation of the FORK() function is a selectable option and enables a more rapid port of many Unix applications to VM/ESA. The CMS command OPENVM SET FORK ON must be issued before running any application that uses the FORK() function. Once the application is successfully ported, performance can be improved by converting the FORK() calls to SPAWN() or some other appropriate replacement.

JAVA VIRTUAL MACHINE, JDK 1.1.1, AND NETREXX

Java is the language of the Internet because of its object code portability. A Java program compiled on any system can execute unchanged on any other platform with a Java Virtual Machine.

It is interesting that the concept of a virtual machine, implemented in IBM's VM/ESA product, should become such a vital element of network computing enablement.

The Java Virtual Machine (JVM) defines a virtual processor architecture with its own instruction set, just as VM/ESA defines a virtual

System/390 processor with a System/390 instruction set. The main difference is that the JVM is completely platform neutral. Provision of a JVM for VM/ESA means that Java applications can execute unchanged on VM/ESA, thereby expanding significantly the portfolio of applications available to VM users.

Many programmers, whose background is solely in high-level procedural languages such as COBOL, FORTRAN, PL/I, etc, may find the object-oriented Java language difficult to learn. However, most VM programmers make heavy use of the REXX language to produce applications on CMS. The NetREXX language, a derivative of REXX, allows programmers to write Java applications in a REXX-like language. The NetREXX reference compiler generates Java source code for subsequent (automatic) compilation by the Java compiler into Java byte-codes. In fact, many existing REXX programs are themselves valid NetREXX programs.

VM/ESA V2 R3.0 Java support is at the Java Developer's Kit (JDK) Level 1.1.1. The support includes:

- Java compiler
- Debugger
- The Java Virtual Machine (Java byte-code interpreter)
- The JDK 1.1.1 class libraries.

The VM/ESA support for Java does not include a Just-In-Time (JIT) compiler or use of the Abstract Windowing Toolkit (AWT) and Java DataBase Connectivity (JDBC) classes for execution (you can, however, compile Java programs that use these classes on VM/ESA). One VM programmer has already reported successful use of Remote AWT (RAWT) components to enable a Java application using AWT methods that is executing on VM to drive a graphical windowing display on a programmable workstation. In practice, the absence of AWT run-time support is frequently immaterial because many Java applications have a client/server structure and AWT classes would only be used by the client component running on a PC or IBM Network Station for animation and graphical presentation. The Beta 2 level code for Java includes full use of the Java Native Interface (JNI).

^{© 1998.} Reproduction prohibited. Please inform Xephon of any infringement.

An IBM International Technical Support Organization (ITSO) redbook about Java and NetREXX support in VM/ESA is currently undergoing final editing. It can be browsed in 'red pieces' format at http:// www.redbooks.ibm.com.

MESSAGE QUEUING CLIENT INTERFACE

The Message Queuing (MQ) Interface is a popular network computing technology that enables applications on different systems and architectures to work together. The MQ application-to-application communication protocol is simple yet powerful, using a queue manager (MQ server) somewhere in the enterprise to allow applications to communicate asynchronously without requiring the requester (client) and server to be connected.

VM/ESA Version 2 Release 3.0 support for MQ enables client or server applications on the network to connect to applications on VM that have implemented the MQ communication protocol. Use of the MQ APIs on VM requires the deployment of an MQ server somewhere in the network.

Using MQSeries clients is an efficient way of implementing MQSeries messaging and queuing. An application can use the Message Queue Interface (MQI) running on one machine with the queue manager running on a different machine. In this model there is no need for a full MQSeries implementation on the client machine, system administration requirements are reduced, and an MQSeries application running on a client can connect to multiple queue managers on different systems.

The VM/ESA MQSeries client will connect to all nineteen IBM and non-IBM platforms that currently support an MQSeries Server installation. Programming language bindings for the MQSeries client include C, COBOL, PL/I, REXX, and Assembler.

For further information, visit the MQSeries product family home page at http://www.software.ibm.com/ts/mqseries.

INTEGRATION OF CMS PIPELINES PRPQ

VM/ESA Version 2 Release 3.0 now incorporates the functionally

richer Pipelines PRPQ as a standard part of the system. New support includes toleration for Pipelines program execution in a multi-tasking environment, TCP stages, and documentation of more Pipelines stages, including the popular Author's Help (AHELP).

Effectively, the VM/ESA ('Endicott') version of CMS Pipelines is merged with the Runtime Distribution ('Copenhagen') version, also known as CMS/TSO Pipelines.

Several message texts have been revised and over 200 new messages added. Return codes are the Copenhagen ones rather than those associated with the DMS messages. The DMS messages are deleted and a cross reference between the old DMS and new FPL message numbers is provided.

The Copenhagen *CMS/TSO Pipelines: Author's Edition* reference is now published as a VM manual, SL26-0018. Author's Help (AHELP) is also documented and supported.

A new CONFIGURE stage and a 'style' concept have been added to let a programmer control any differences between the two Pipelines versions. To determine how a pipeline should behave in other instances where there traditionally used to be a difference between the Copenhagen and the Endicott versions, defaults are now maintained, derived from variables set in the GLOBALV group FPL (by default).

Toleration support for CMS multi-tasking means that a pipeline now supports recursions on different processes and threads. However, a pipeline has no concept of the 'current thread' – pipeline sets run completely in parallel in their respective threads. How control passes between threads is of no concern to the pipeline.

A new stage named DATECONVERT will perform date conversion and validation.

The TCP stages from the Runtime Distribution version can be used to program TCP/IP sockets server applications. For example, TCPLISTEN listens on a TCP port. It listens for and accepts connection requests using the socket interface to TCP/IP. The socket representing the connection is then transferred to a TCPDATA stage, which exchanges data with the client.

EXTENSIONS TO YEAR 2000 SUPPORT

Besides the DATECONVERT Pipelines stage, additional Year 2000 conversion functions in VM/ESA Version 2 Release 3.0 include a utility to correct the century indicators for CMS files and 4-digit year support in the user NETLOG file.

DATECONVERT is easy to use and provides date conversion, validation, and windowing functions. It allows a programmer to rapidly convert and validate large amounts of date data. DATECONVERT supports all the REXX date formats, plus additional formats. Internally, it uses the DateTimeSubtract CSL routine, but provides a simpler interface for date format conversions.

The DateTimeSubtract routine (DMSDTS) has been updated in the new release of VM/ESA. See the 'CSL Considerations' section of the Runtime Library Distribution page at http://pucc.princeton.edu/~pipeline/ for notes on invoking the correct level of DMSDTS.

Two new commands are provided with VM/ESA Version 2 Release 3.0 that set the internal century information stored with mini-disk or SFS files. The commands are FIXCENT for mini-disks, and FILESERV FIXCENT for SFS file pools. These commands set the century according to a sliding window of '-50,+49' applied to the 2-digit year that is stored with the file information.

Setting the century information is not needed as part of a normal migration procedure, since all data that is created on a non-Year 2000-ready release of VM/ESA, when IPLed on a Year 2000-ready release of VM/ESA, will default to 19xx. Setting the century is only needed if, after testing, some files have 4-digit years that appear as 20xx but should be 19xx. The century will be reset according to the sliding window described above.

Although IBM provides this facility for migration and test, it does not recommend using production data and files when testing with a system date set in the Year 2000 or later, or sharing data and files between production systems and Year 2000 test systems. Data and files which are used for Year 2000 testing should be isolated from any production environment.

Beginning with VM/ESAVersion 2 Release 3.0, when a new NETLOG file is created, entries written to the file will contain dates in ISODATE format (yyyy-mm-dd). NETLCNVT will convert the dates in an existing NETLOG file from 2-digit years to 4-digit years and *vice versa*.

INTEGRATED LANGUAGE ENVIRONMENT

In VM/ESA Version 2 Release 3.0, IBM has extended the 'standard' package to include the entire Language Environment. LE run-time libraries are needed by many IBM and non-IBM applications and subsystems; in the past any VM customer who wanted to use those products had to purchase LE as well. With the inclusion of LE in the base of VM, this additional purchase will no longer be necessary.

In addition to the Common Execution Library (CEL) support provided for OpenEdition VM/ESA in previous Version 2 releases, the run-time requirement for VM compilers such as IBM C for VM/ESA, IBM COBOL for MVS and VM, and IBM PL/I for MVS and VM is now satisfied.

OS/390 GUEST PARALLEL SYSPLEX TESTING SUPPORT

Many VM installations exploit VM as a hipervisor for pre-production testing of MVS and OS/390 systems. As MVS and OS/390 have moved into the coupled sysplex environment, the demand has grown to provide a similar capability under VM. With VM/ESA Version 2 Release 3.0, it is now possible to simulate coupled sysplexes within a single VM system image. This capability is dependent on IBM's Coupling Facility Control Code (CFCC), which is Licensed Internal Code (LIC) on the IBM Multiprise 2000 Server and the IBM Parallel Enterprise Server Generation 3 and Generation 4. These ranges of machines (at the proper engineering change levels) are supported for guest parallel sysplex testing under VM/ESA.

The CFCC runs in a special Coupling Facility Virtual Machine (CFVM). No other special hardware is required. Coupling links (CF channels) and external coupling facilities are neither required nor supported by VM.

^{© 1998.} Reproduction prohibited. Please inform Xephon of any infringement.

CP simulates the message facility used in a real parallel sysplex. Virtual message devices are employed to transfer data and commands between the CF service machine(s) and the coupled guest virtual machines. They are defined in a SPECIAL Directory Control statement for a virtual machine participating in a simulated sysplex (ie with the CFUSER parameter on the OPTION Directory Control statement).

VM/ESA guest coupling simulation does not support or simulate sysplex timers (ETR). When running in a VM/ESA environment, all virtual machine TOD clocks are synchronized with the system TOD clock. This implicit synchronization allows all MVS images running in a sysplex on VM/ESA to have identically set TOD clocks without the use of an ETR.

A simulated sysplex environment can even run with a date and time that is different from the system date and time. The CP SET VTOD command makes it possible to perform Year 2000 testing of a parallel sysplex environment running second level on a VM/ESA production system without having to IPL the production system with a Year 2000 date.

VM allows the definition of a simulated coupled sysplex up to the architectural maximum of 32 coupled guests. Each coupled guest can be connected to a maximum of eight CFVMs.

OTHER CMS ENHANCEMENTS

Apart from CMS enhancements discussed earlier, there are other minor changes.

The EXECUTE macro has been rewritten as a compiled REXX program. This will provide performance improvements when EXECUTE is issued with the CMS FILELIST and RDRLIST commands. More EXECs have been moved into the CMSINST segment. The VM Graphical User Interface (VM GUI) now supports 32-bit workstation agents for Windows 95 and Windows NT. It also provides an option to eliminate the initial security prompt for authorized host user-ids by keeping the authorization list on the workstation.

SUMMARY

The focus of VM/ESA Version 2 Release 3.0 is chiefly on support of the network computing model and e-business enablement. With major enhancements to TCP/IP, extended NFS support, Java and NetREXX, OpenEdition APIs, and an MQSeries client, plus excellent Web serving solutions from IBM business partners, VM is well positioned to maintain its role as a flexible, efficient, functionally rich, high-performance server platform.

Mouse on the mainframe

Traditional 3270-based applications are usually designed to accept text which is typed into certain screen locations, and perhaps to respond when PF keys are pressed. Users require adequate keyboarding skills, along with a knack for remembering (often complex) command syntax.

The programs described here were designed to be manipulated with a workstation mouse and consequently demonstrate an alternative approach to 3270 application design. These 'pointer enabled tools' exploit a simple synergy between 3270 emulation software and hostbased applications. The resulting interface is fast, intuitive, and highly functional. Users type less, make fewer errors, and as a result are more productive.

BACKGROUND – TO THE MAC AND BACK

In 1989 I swapped my monochrome green IBM 3178 terminal for a Macintosh IIfx and I suddenly understood the advantages of a mouseclickable GUI interface. Within a year or so, I had abandoned VM/CMS as a personal computing platform, except for e-mail (PROFS and MailBook). I learned MS Excel, Aldus Persuasion, Superpaint – what wonderful tools!

However, around 1992 (when mainframes were dying, remember?) I realized that:

- It was taking me longer to complete text-only tasks.
- It was awkward to share such files with co-workers who used PCs, Unix workstations, and 3270 terminals.
- I could not work from home without borrowing a Mac (my home computer was a PS/2).
- I could not easily check on our MVS system.
- Apart from HyperCard, I had no programming tools and when my Mac was down (which admittedly was infrequently) I could not work at all (at least not on *my* files).

For many tasks, I preferred the Macintosh's software, but for a lot of routine chores, using the small system was simply inefficient. I found myself drifting back to CMS.

At the same time, despite the proliferation of microcomputers on campus, thousands of our students, faculty, and staff continued to use VM/CMS commands and the traditional 3270 interface for e-mail and other tools such as MINITAB, SAS, and FOCUS.

I wanted the best of both worlds. So I asked my staff why we couldn't have a more user-friendly mainframe.

Because my questions generally went unanswered – and because I wanted to learn how to program in REXX – I started playing around with some (in hindsight) rather awkward menuing programs. Menus led to XEDIT macros and to CMS windows and so on. Then, in 1996, I stumbled across the fact that some of what I had written could be manipulated by positioning the 3270 cursor with a workstation mouse and clicking with the right mouse button. Pure chance. The serendipitous convergence of:

- My interest in making VM/CMS easier to use.
- REXX code written to respond to the position of the cursor when the ENTER key is pressed.
- 3270 terminal emulation software which by default configured the right mouse button action in a certain way.
- Bumbling fingers which pressed the wrong mouse button!

With tongue in cheek, I started calling these programs 'Pointer Enabled Tools' or 'PETs' and the name stuck.

EXAMPLES OF MOUSE-CLICKABLE SOFTWARE

Excuse me? Did you say mouse-clickable software?

The QCMDS application presents a list of commands (actually, descriptions of commands) in a CMS window. This is shown in Figure 1. By using arrow keys, you can reposition the 3270 cursor on any menu item, press the ENTER key, and the corresponding command

IBMTOOLS QCMDS * 1 to 16 of 16 Select a command from the menu. CMS HELP - Information About VM/CMS Commands DIRLIST - List Disks and Directories FILELIST - List Personal Disk Files RDRLIST - List Personal Reader Files SENDFILE - Send Files to Another Account CP IND - System Busy Indicators CP IND USER - Usage Indicators for this Userid CP Q TERM - Virtual Terminal Characteristics 0 DISKS - linked Disks Q LOGMSG - Log Message QUR - Reader, Punch, Printer Q USERS - Number of Logged on Users H CPQUERY - Help for CP Queries H CMSQUERY - Help for CMS Queries P 1=Help 2=Refresh 3=Quit 4=EditMenu F 7=Backward 8=Forward 9=Top 1Ø=Bottom OCMDS

Figure 1: QCMDS application

is executed. Press a PF key, as labelled on the two lines at the bottom of the window, and QCMDS responds properly. Simple enough?

Now, if the mouse action associated with clicking your right mouse button is set properly, you can point to an item on the QCMDS menu with the workstation pointer and select that item by clicking with the right mouse button. In the case of QCMDS, you can also 'point and click' on the PF key labels to invoke the functions associated with those PF keys, and you can 'point and click' outside the QCMDS window to close that window.

The PFLIST application, which displays a list of disk files in its primary window, is a mouse-clickable alternative to FILELIST. This is shown in Figure 2.

Imagine the following:

- You can open a file to XEDIT by clicking on the filename.
- You can sort the list of files by clicking on any of the column headers (ie filename, filetype, fm format, etc).
- You can activate the functions associated with the PF keys by clicking on the PF key labels toward the bottom of the screen.
- You can view a list of files on another accessed disk (or directory)

by clicking on one of the active filemodes shown on the bottom line:

Write the CMS code to respond to the position of the cursor when the ENTER key is pressed, configure your 3270 emulation software to 'set the 3270 cursor' and 'press ENTER', and there you have it – mouse-controllable software on CMS.

USE MY MOUSE ON THE MAINFRAME? IT CAN'T BE DONE!

Some might consider that using a PC or Unix workstation mouse to control CMS software is something close to heresy!

In presenting the ideas behind PETs, I generally run into two very different reactions. When I demonstrate the tools, people are surprised to learn that it can be done at all. They are pleased with the ease of use and the response time. I've heard the comment, "Wow!", on more than occasion.

But when I try to describe what I'm doing over the telephone, I generally run into what seems to be a psychological barrier. The words '3270' and 'mouse' not only don't go together in a sentence, they don't even belong in the same conceptual universe – until now that is.

At the beginning of this project, I realized that there were a couple of fundamental issues that we must deal with. Firstly, 3270 traditionalists have come to believe that pressing the ENTER key is usually a pretty harmless act – and often quite helpful. Press ENTER and the cursor returns to the command line, for example. With PETs, pressing the ENTER key invokes one of many possible actions, determined specifically by the location of the cursor when the deed is done. Pressing ENTER is *not* a 'soft reset' any more.

Secondly, we 3270 traditionalists place our hands on the keyboard, not on the mouse, when the green screen pops up. Long-standing habits make it difficult for us to 'go for the mouse' as the first option, the way we do when using MS Word or Netscape Navigator. To get the most from PETs, we have to reach for the mouse.

Thirdly, having just a few pointer-enabled tools won't do.

Psychologically it is awkward and frustrating to have to switch between a 'primarily typing' interface and a 'primarily mousecontrolled' interface. For PETs to catch on, a critical mass of useful software, which shares a common look and feel, would have to be developed. A critical mass of pointer-enabled software exists only when you can spend most of your day in mouse mode.

Finally, the design of these tools requires a rethink in the way in which users interact with the applications. Traditionally, 3270 screens accept typed data and/or commands; PF keys are often defined as shortcuts for a dozen or so functions. And that's about it. With PETs, any area, line, column, or even a single character on the screen becomes a potential control. Taking this to the extreme, a single (80 x 24) 3270 screen can contain 1,920 clickable control points!

A BLEND OF TWO INTERFACE STYLES

PETs are intended to serve two kinds of users:

- Those who like using a mouse (or other pointing device).
- Those who like using traditional 3270 keyboard functions (commands, PF keys, arrow keys, the ENTER key).

While some usability enhancements are obviously intended for use with a mouse, all functions are available as well on a dumb terminal. In a very real sense, the PETs style interface blends these two approaches together into a fast, non-graphical package that can enhance the productivity of all users.

ENABLING TECHNOLOGIES

PETs are written in REXX and make extensive use of CMS virtual screens and windows as well as CMS Pipelines and CP/CMS commands. The XEDIT macros, of course, make use of XEDIT subcommands and XEDIT internal variables. A few PETs are designed as 'front-ends' to other applications (eg IBM's OfficeVision or Script/VS, or L-Soft's Listserv), so naturally those other applications are required if the 'front-end' PETs are to be useful.

Some of the file management tools use the FULLDATE option of the

LISTFILE command, so CMS must be at a level to support this function (but since we're all getting ready for Year 2000, this should not be a problem for long!).

While PETs can be used as traditional 3270, keyboard-reliant applications from fixed-function 3270 terminals, the special advantages of PETs are unavailable if one does not use a 'PETs-friendly' 3270 emulator running on a PC, Macintosh, or Unix workstation. To be 'PETs-friendly', a 3270 emulator must allow some mouse action to set the 3270 cursor to any location on the screen and then to emulate pressing the ENTER key. I find it most convenient if a single click of one mouse button (the right mouse button on my PC) performs both these functions, but variations exist. Some emulators implement the required functions with two clicks of the left mouse button, by default. Other emulators require that the 3270 commands be configured into a macro, which is then assigned to the mouse action. Unfortunately, some emulators do not appear to provide a way to properly configure the mouse action at all.

GENERAL DESIGN CHARACTERISTICS

PETs programs derive from precursor attempts to make VM/CMS more 'user-friendly' and they do make working on the mainframe considerably easier. Programs incorporate a number of key ideas:

- Considerably less typing is required.
- Mouse-clicking for navigation and functional selection is enabled.
- CMS windows are used extensively.
- Menus are a key component.
- Menus and colours are easy to customize on-the-fly.
- All commands can be selected from menus or entered on command lines.
- Significant usability enhancements are added.
- The interface is fast.
- Colours and PF keys are used consistently.

- Windows have a consistent (and familiar) look and feel.
- Activity logs can record what you do so that you can do it again more quickly.
- Many functions are generic and can be re-used in new applications.
- Programs are completely compatible with other VM/CMS tools PETs menus can include non-PETs applications.
- A critical mass of software is now available to enable users to do most of their CMS work from within PETs.

In general, I try to follow several usability rules:

- It is better to click than to type.
- It is better to click once than to click more than once.
- It is better to be simple than to be cryptic.
- It is better to rely on screen cues and human intuition than on documentation.

PETSHELL – A STARTING POINT FOR ALL CMS WORK

A GUI or non-GUI desktop offers a starting point for one's computing efforts. Icons and other screen cues invite certain actions which lead to programs and files. Human operators need to *recognize* what they see rather than *recall* commands and file names, and it is easier to do the former than to do the latter. So a visually helpful starting point is comforting to most people.

The PETSHELLEXEC offers such a starting point (although there are others). PETSHELL displays information about the current session, a number of clickable, colour-coded 'hotspots' which invoke useful tools or display additional menus, and a command line which accepts any CP or CMS command or EXEC. A command 'logging space' in the centre of the window retains the commands which have been entered on the PETSHELL command line. In the example shown in Figure 3 the PETSHELL window displays the lines:

XEDIT PROFILE EXEC Ready(Ø) QUERY RGE

```
Menu: DEFAULT PETSHELL * 20 Jun 1998 09:59:51
                                                             RGE AT UCONNVM
 Enter CP/CMS commands.
                ----- CMSHELP DISCONN LOGOFF PAPPS PNOTES

 ===>
                            PETSHELL
Figure 3: PETSHELL window
```

Ready(Ø) FILELIST Ready(Ø)

These represent three commands previously entered on the command line. One of these commands could be re-invoked exactly as before by clicking on the line containing the command. The text of the command can be altered before selection by typing over the previous command.

PETSHELL can be invoked by entering its name on the CMS (or XEDIT) command line or on any command line displayed by other PETs. For routine use, a CMS PF key can be defined to launch PETSHELL – and to use PETSHELL as the standard CMS desktop, you would simply invoke PETSHELL from your PROFILE EXEC as follows.

```
/* Profile Exec */
```

```
'SET PFØ1 IMMED EXEC PETSHELL'
Push 'EXEC PETSHELL'
Exit
```

HOW FAR CAN PETS GO?

Obviously, the PETs interface is a text-only interface – but then a good deal of the world's business is conducted using text. While graphics are sometimes very important, most graphics seen today on the Web and elsewhere are merely icing on the content cake, and the cake consists of words.

For example, graphical calendars are appealing, but text-based calendars, like the one offered by the PCAL EXEC (shown in Figure 4) work quite nicely.

By clicking on PF4 or PF5 (4 = Previous, 5 = Next) the four month calendar is shifted forwards or backwards by one month. In other

Figure 4: PCAL calendar

applications, a user might select a date by clicking on it rather than by typing it.

The range of text-based applications that could benefit from the PETs style interface is very broad. We are more likely to be limited by our imaginations than by the basic technology, which is readily available.

ACKNOWLEDGEMENTS

I would like to express my appreciation for the work done to create the 3270 emulation software, *TCP3270 for Windows/NT Version 3.10* (Copyright McGill University, 1991-1996), whose thoughtful author(s) assigned to the right mouse button the mouse action required for PETs programs to work in the way they do.

Editor's note: in a future article, the author will focus on the technical aspects of PETs.

A full screen console interface – part 3

Editor's note: this month we continue the code for the full screen console interface for Disconnected Service Machines (DSM). This article is an extensive piece of work which will be published over several issues of VM Update. It was felt that readers could benefit from the entire article and from the individual sections. Any comments or recommendations would be welcomed and should be addressed either to Xephon or directly to the author at fernando_duarte@vnet.ibm.com.

IBM has announced Version 2 Release 3 of its VM server platform, formerly VM Productivity System (VMPS). This includes a maintenance upgrade of VM/ESA 2.3.0 to 2.4.0 and OfficeVision 1.3.0 to 1.4.0, plus new products including COBOL for MVS and VM, and Language Environment for OS/390 and VM. DisplayWrite/370, BookManager Build, BookManager Read, and Bulletin/VM are no longer included in the suite.

VM/ESA improvements include a Java Virtual Machine for creating and porting Java applications, an MQ client interface for application-to-application communication across different systems and architectures, integration of CMS Pipelines PRPQ, TCP/IP performance enhancements, and added support for the year 2000.

OfficeVision/VM Release 4.0 is now Year 2000 ready. The default panels shipped with OV Release 4 will be those supporting Shared PROFS.

For further information contact your local IBM representative.

* * *

Sterling Software has launched a new VM skills service that includes training and education, software implementation and consulting, and assessments for Year 2000 compliance.

The courses cover topics such as VM/ESA technology, Internet and Web technology, systems management, and the company's own VM products.

For further information contact: Sterling Software, 1800 Alexander Bell Drive, Reston, VA 22091, USA. Tel: (703) 264 8000. Sterling Software, 64 London Road, Reading, Berkshire, RG1 5AS, UK. Tel: (0118) 975 0055. URL: http://www.vm.sterling.com.

* * *

IBM has announced High Level Assembler Release 3 for VM, MVS, and VSE, to replace all previous System/370 and System/390 Assemblers. This includes tools for developing and maintaining all Assembler applications, converting symbolic source statements to machine language object code with extensive checks for common coding errors. There is support for ESA/390 IEEE binary floating-point instructions, data, and additional floating point registers, plus new diagnostic and cross-reference features and a range of language enhancements.

The USING statement has been enhanced to allow a limit to the resolution range to be specified, and a new ACONTROL statement allows fine-grained controls over certain options within the source program. Its status may be saved and restored with the PUSH and POP instructions. A new INFO option provides details of the current service status of the user's Assembler, and a cross reference of general register usage has tags to indicate usage types.

For further information contact your local IBM representative.
